## Definition

Let  $X$  be a smooth, irreducible, projective variety defined over  $\mathbb{F}_\ell$ . The **Hasse-Weil zeta function** for  $X$  is defined as:

$$Z(X, u) = \exp \left( \sum_{n=1}^{\infty} \frac{\#X(\mathbb{F}_{\ell^n})}{n} u^n \right) = \prod_{x \in [X]} \frac{1}{1 - u^{\deg(x)}},$$

where the product is defined over the closed points of  $X$ .

## Definition

Let  $X$  be a smooth, irreducible, projective variety defined over  $\mathbb{F}_\ell$ . The **Hasse-Weil zeta function** for  $X$  is defined as:

$$Z(X, u) = \exp \left( \sum_{n=1}^{\infty} \frac{\#X(\mathbb{F}_{\ell^n})}{n} u^n \right) = \prod_{x \in [X]} \frac{1}{1 - u^{\deg(x)}},$$

where the product is defined over the closed points of  $X$ .

Again, these zeta functions have a version of the Riemann hypothesis, now known by work of Deligne (and others).

Abstract isogeny graphs provide a framework for addressing these issues:

## Definition

An *abstract isogeny graph* is the following collection of data:

- A set  $X$  of vertices;
- a set  $Y$  of edges;
- functions,  $s, t : Y \rightarrow X \times X$ ;
- a function  $J : Y \rightarrow Y$ ; and
- a function  $L : X \rightarrow X$ ,

such that  $s(J(e)) = t(e)$  and  $t(J(e)) = L(s(e))$  for all  $e \in Y$ .

## Theorem

Let  $\Gamma = (X, Y, J, L)$  be an abstract isogeny graph with regular out degree  $d$  and adjacency matrix  $A$ . Then  $\zeta_\Gamma(u)$  is given by:

$$\frac{(1 - u^2)^{C_1(L)}(1 + u)^{-C_1(J)} \prod_{k>1} (1 - (-1)^k u^{2k})^{C_k(L)} (1 - u^k)^{-C_k(J)}}{\det(1 - Au + u^2(d - 1)L)}$$

# Orientable graphs associated to abstract isogeny graphs

For both simplification of the previous formula, and the statement of the next, we use the *orientable graphs* associated to an abstract isogeny graph  $\Gamma$ .

For both simplification of the previous formula, and the statement of the next, we use the *orientable graphs* associated to an abstract isogeny graph  $\Gamma$ .

## Definition

Let  $\Gamma = (X, Y, J, L)$  be an abstract isogeny graph. We define  $\sim_X$  to be the smallest equivalence relation on  $X$  such that  $x \sim_X Lx$  for all  $x \in X$ , and  $\sim_Y$  to be the smallest equivalence relation on  $Y$  such that  $y \sim_Y J^2y$  for all  $y \in Y$ . The *orientable graphs associated to  $\Gamma$*  are

$$\begin{aligned}\Gamma^{+1} &= (X / \sim_X, Y / \sim_Y - \{[y] : J[y] = [y]\}) \text{ and} \\ \Gamma^{-1} &= (X / \sim_X, Y / \sim_Y \sqcup \{[y] : J[y] = [y]\})\end{aligned}$$

# Orientable graphs associated to abstract isogeny graphs

In many cases, we can simplify our formula for  $\zeta_{\Gamma}(u)$  using these orientable graphs:

In many cases, we can simplify our formula for  $\zeta_\Gamma(u)$  using these orientable graphs:

## Theorem

Let  $\Gamma$  be a  $d$ -regular abstract isogeny graph for  $d \geq 1$ , and suppose that the permutation induced by  $J$  is an involution and  $s(J^2y) = s(y)$  for every edge  $y \in Y$ . Then we have

$$\zeta_\Gamma(u) = \frac{(1+u)^{\chi(\Gamma^{-1})}(1-u)^{\chi(\Gamma^{+1})}}{\det(\text{id}_{\mathbb{C}^\times} - uA + u^2Q)}.$$
